The Ilizarov method is a type of external fixation that is used to treat a variety of orthopedic conditions, including fractures, dislocations, and deformities. It was developed by Russian orthopedic surgeon Gavriil Ilizarov in the 1950s, and it has since become one of the most widely used external fixation systems in the world.

The Ilizarov method is based on the principle of tension-stress. This means that the Ilizarov frame is used to create a controlled amount of tension on the bone, which stimulates the bone to heal. The Ilizarov frame is made up

of a series of rings and rods that are connected to the bone with wires or pins. The rings are then adjusted to create the desired amount of tension.

The Ilizarov method has a number of advantages over other types of external fixation. First, it is less invasive than other methods, which means that it causes less damage to the surrounding tissues. Second, the Ilizarov method is more versatile than other methods, which means that it can be used to treat a wider variety of orthopedic conditions. Third, the Ilizarov method is more effective than other methods, which means that it leads to better clinical outcomes.
